Abstract

This paper derives fundamental results for data validation in the presence of imprecisely known correlations. Given a constraint on the maximum absolute correlation of a given estimate and measurement data, a tight upper bound for the joint covariance matrix is derived, which finally yields a modified Mahalanobis distance. The special cases of one-dimensional and two-dimensional random variables are discussed.

Keywords: Data Validation; Stochastic Uncertainties; Mahalanobis Distance; Imprecisely Known Correlations; Covariance Bounds

1 Introduction

Data validation is a crucial task in most filtering applications: Given an estimate of the unknown state, a noisy measurement, and a quantification of the uncertainty of the estimate and the measurement data, data validation has to decide if the measurement data is compatible with the given estimate, and thus can be used for filtering. Stochastic data validation for linear systems corrupted by Gaussian noise is typically based on the Mahalanobis distance [1]. For calculating the Mahalanobis distance, the cross–covariance of the given estimate and the measurement data has to be known. However, in many applications, the cross–covariance is not known precisely. Only constraints on the maximum correlation coefficient are given.

This paper derives a modified Mahalanobis distance that allows for data validation when only constraints on the maximum correlation coefficient are known. It is based on a tight bound for the joint covariance of two random vectors with unknown but constrained cross–correlation derived in [3]. Applications of this data validation scheme include data association problems in simultaneous vehicle localization and map building [6].

2 Problem Formulation

We are given two random vectors \( \mathbf{x} \in \mathbb{R}^N, \mathbf{y} \in \mathbb{R}^M \) with expected values

\[
E\{\mathbf{x}\} = \hat{\mathbf{x}}, \quad E\{\mathbf{y}\} = \hat{\mathbf{y}}
\]

and individual covariances

\[
\text{Cov}\{\mathbf{x}\} = C_{xx}, \quad \text{Cov}\{\mathbf{y}\} = C_{yy},
\]

where \( \mathbf{x} \) and \( \mathbf{y} \) are assumed to be correlated. Their cross covariances \( \text{Cov}\{\mathbf{x}, \mathbf{y}\} = C_{xy} \) and \( \text{Cov}\{\mathbf{y}, \mathbf{z}\} = C_{yz} \), however, are not explicitly known. Correlations between \( \mathbf{x} \) and \( \mathbf{y} \) are modelled by a total correlation coefficient \( r_{xy} \), which is constrained according to

\[
|r_{xy}| \leq r_{\text{max}} .
\]

Of course, this also includes the case of completely unknown correlation between \( \mathbf{x} \) and \( \mathbf{y} \) for \( r_{\text{max}} = 1 \).

Hence, a constraint for the cross covariances is given by

\[
C_{yz} C_{xx}^{-1} C_{xy} \leq r_{\text{max}}^2 C_{yy} ,
\]

where, in general, for two positive definite matrices \( \mathbf{A} \) and \( \mathbf{B} \), an expression of the form \( \mathbf{A} \preceq \mathbf{B} \) (\( \mathbf{A} \succeq \mathbf{B} \)) is interpreted as \( \mathbf{A} – \mathbf{B} \) positive definite (positive semi–definite). By defining the matrix

\[
\mathbf{C} = r_{\text{max}}^2 \mathbf{C}_{yy} - C_{yz} C_{xx}^{-1} C_{xy} ,
\]

(2) is equivalent to

\[
\det (\mathbf{C}(1 : i, 1 : i)) \geq 0
\]

for \( i = 1, \ldots, M \) according to the Sylvester criterion.

We now assume that an estimate of \( \tilde{\mathbf{x}} \) is available and new information in the form of measurement data \( \tilde{\mathbf{y}} \) is obtained. We also assume that the (unknown) true vectors \( \tilde{\mathbf{x}} \) and \( \tilde{\mathbf{y}} \) are related by a measurement equation of the form

\[
\mathbf{H}_{\tilde{x}} \tilde{\mathbf{x}} = \mathbf{H}_{\tilde{y}} \tilde{\mathbf{y}} ,
\]

(3) where \( \mathbf{H}_{\tilde{x}} \) and \( \mathbf{H}_{\tilde{y}} \) are known matrices of appropriate dimensions.

Now, the following question arises: Is \( \mathbf{y} \) a valid measurement, i.e., can it be explained by the measurement equation and be used for estimation purposes or is it an outlier? Of course, this question can only be answered with a certain probability of, say 99 %, of being true. The task of data validation is complicated by the fact, that the correlation between \( \tilde{\mathbf{x}} \) and \( \tilde{\mathbf{y}} \) is not known precisely.

The problem is now solved in two steps. In the first step, covariance bounds for two random variables with imprecisely known correlation are derived. In the second step, these bounds are used to derive a modified Mahalanobis distance for data validation in the presence of imprecisely known correlations.
Figure 1: The admissible values for $\eta(\kappa)$ and $\kappa$ resulting from Lemma 3.1.

3 Covariance Bounds

In this section, we are concerned with deriving covariance bounds for the joint covariance of two correlated random variables with imprecisely known correlation. Hence, our goal is now to find a family of bounding covariances $B$ with

$$B \geq C(r_{xy}) \tag{4}$$

for all possible joint covariances $C(r_{xy})$ defined by

$$C(r_{xy}) = \begin{bmatrix} C_{xx} & C_{xy} \\ C_{yx} & C_{yy} \end{bmatrix}$$

with $r_{xy}$ according to (1) and $C_{xy}, C_{yx}$ such that (2) holds.

For deriving the desired covariance bounds we use the fact that the union of the 1-sigma–bounds of all possible joint covariances forms a convex set aligned with the coordinate axes. Hence, the cross covariances of the bounding covariance matrix have to be zero matrices. For the simplest case of two scalar random variables $x$ and $y$ this is visualized in Figure 2.

In addition, for achieving an upper bound, the covariance matrices $C_{xx}$ and $C_{yy}$ have to be individually scaled. Combining both conditions yields

$$B = \begin{bmatrix} k_x C_{xx} & 0 \\ 0 & k_y C_{yy} \end{bmatrix} \tag{5}$$

$k_x, k_y$ have to be selected in such a way that (4) holds.

Theorem 3.1 The scale factors $k_x, k_y$ in (5) are given by

$$k_x = \frac{1}{\eta - \kappa}, \quad k_y = \frac{1}{\eta + \kappa} \tag{6}$$

with

$$\kappa^2 \leq \frac{1 - 2\eta}{1 - r_{max}^2} + \eta^2 \tag{7}$$

and

$$0.5 \leq \eta \leq \frac{1}{1 + r_{max}} \tag{8}$$

Proof. For proving (4), the difference matrix

$$D = B(\eta, \kappa) - C(r_{xy})$$

$$= \begin{bmatrix} \frac{1}{\eta - \kappa} C_{xx} & 0 \\ 0 & \frac{1}{\eta + \kappa} C_{yy} \end{bmatrix} - \begin{bmatrix} C_{xx} & C_{xy} \\ C_{yx} & C_{yy} \end{bmatrix}$$

$$= \begin{bmatrix} \left(\frac{1}{\eta - \kappa} - 1\right) C_{xx} & -C_{xy} \\ -C_{yx} & \left(\frac{1}{\eta + \kappa} - 1\right) C_{yy} \end{bmatrix}$$

is considered. According to Sylvester’s criterion, the matrix $D$ is positive semi–definite, if the determinants of all submatrices $D(1 : N + i, 1 : N + i)$ for $i = 1, \ldots, M$ are larger than or equal to zero. $\left(\frac{1}{\eta - \kappa} - 1\right) C_{xx}$ is positive definite and does not need to be tested. The determinants are given by

$$\det(D(1 : N + i, 1 : N + i))$$

$$= \det\left(\left(\frac{1}{\eta - \kappa} - 1\right) C_{xx}\right) \det\left(\left(\frac{1}{\eta + \kappa} - 1\right) C_{yy}(1 : i, 1 : i)\right)$$

$$- \left(\frac{1}{\eta - \kappa} - 1\right) C_{yx}(1 : i, 1 : N) C_{xy}(1 : N, 1 : i)$$

With (2) we obtain

$$\det\left(\left(\frac{1}{\eta - \kappa} - 1\right) \left(\frac{1}{\eta + \kappa} - 1\right) - r_{max}^2\right) C_{yy}(1 : i, 1 : i) \geq 0$$

for $i = 1, \ldots, M$, which is equivalent to

$$\left(\frac{1}{\eta - \kappa} - 1\right) \left(\frac{1}{\eta + \kappa} - 1\right) - r_{max}^2 \geq 0$$

and yields (7). The constraint on $\eta$ in (8) then follows by claiming a non–negative right–hand–side in (7). □

The parameter set for $\eta$ and $\kappa$ from the Theorem is redundant in the sense that it specifies scaled variants of a bounding covariance with the same form and orientation. Hence, it is sufficient to restrict attention to the smallest of these scaled variants. The appropriate parameter values are specified in the following Lemma.

Lemma 3.1 A family of bounding covariances $B(\kappa)$ depending on a parameter $\kappa$ is given by (5) with $k_x, k_y$ in (6). The parameter $\kappa$ may vary according to

$$|\kappa| \leq 0.5 \quad .$$

$\eta$ is a function of $\kappa$ given by

$$\eta(\kappa) = 1 - \sqrt{r_{max}^2 + \kappa^2 (1 - r_{max}^2)^2} \tag{10}$$

and

The admissible values for $\eta$ and $\kappa$ resulting from Lemma 3.1 are visualized for different values of $r_{max}$ in Figure 1.
Data validation in the case of completely unknown correlations is similar to testing the overlap of two ellipsoids, which has been treated in [5, 8]. Efficient analytic solutions based on the ideas in [7] are given in [2].

### 4.1 Special Case: One-dimensional Random Variables

We now consider scalar random variables $x$ and $y$ with variances $C_{xx}$ and $C_{yy}$, respectively.

**EXAMPLE 4.1** For two scalar random variables $x$ and $y$ with individual variances $C_{xx} = 9$ and $C_{yy} = 4$, some members of the family of possible joint covariance matrices for different constraints on the maximum absolute correlation coefficient are visualized in Figure 2 by plotting the respective 1-sigma-bounds.

The covariance bound $B(\kappa)$ for the true joint covariance $C(\kappa)$ is given by

$$B(\kappa) = \begin{bmatrix} \frac{1}{\eta(\kappa)-\kappa}C_{xx} & 0 \\ 0 & \frac{1}{\eta(\kappa)+\kappa}C_{yy} \end{bmatrix} .$$

**EXAMPLE 4.2** The covariance bounds for the two scalar random variables in Example 4.1 are shown in Figure 3.

With

$$H_x x = H_y y,$$
the modified Mahalanobis distance is given by
\[
d(\kappa) = \frac{(\eta^2(\kappa) - \kappa^2)}{(\eta(\kappa) + \kappa)} \left( H_x x - H_y y \right)^2
\]
\[
+ \frac{H_x^2 C_{xx} + (\eta(\kappa) - \kappa) H_y^2 C_{yy}}{(\eta(\kappa) + \kappa)}.
\]

**Remark 4.1** In the case of one-dimensional random variables, the optimal \( \kappa \) can be calculated without knowledge of the actual measured values \( x \) and \( y \). It just depends upon the actual values of the variances \( C_{xx} \) and \( C_{yy} \).

### 4.2 Special Case: Two-dimensional Random Variables

We consider two two-dimensional random vectors \( \tilde{x} \in \mathbb{R}^2 \) and \( \tilde{y} \in \mathbb{R}^2 \). The individual covariance matrices \( C_{xx} \) and \( C_{yy} \) are assumed to be known. The correlation between \( x \) and \( y \) is not known precisely and characterized by a total correlation coefficient constrained according to \( |r_{xy}| \leq r_{\text{max}} \).

A simple method for generating valid joint covariance matrices

\[
\text{Cov} \left\{ \begin{bmatrix} \tilde{x} \\ \tilde{y} \end{bmatrix} \right\} = \begin{bmatrix} C_{xx} & C_{xy} \\ C_{yx} & C_{yy} \end{bmatrix}
\]

works as follows. \( C_{xy} \) with \( C_{xy} = C_{yx}^T \) contains four unknown elements. These elements are generated based on individual correlation coefficients defined by

\[
r_{11} = \frac{C_{xy,11}}{\sqrt{C_{xx,11} C_{yy,11}}} \quad r_{12} = \frac{C_{xy,12}}{\sqrt{C_{xx,11} C_{yy,22}}}
\]
\[
r_{21} = \frac{C_{xy,21}}{\sqrt{C_{xx,22} C_{yy,11}}} \quad r_{22} = \frac{C_{xy,22}}{\sqrt{C_{xx,22} C_{yy,22}}},
\]

which may vary according to \( r_{11}, r_{12}, r_{21}, r_{22} \in [-r_{\text{max}}, r_{\text{max}}] \). Random values for these correlation coefficients are generated which are uniformly distributed in the interval \( [-r_{\text{max}}, r_{\text{max}}] \). Based upon these values, tentative entries of the cross covariance matrices \( C_{xy} \) and \( C_{yx} \) are calculated. These tentative entries are validated by means of (2). The method is summarized in Figure 4.

**Example 4.3** We consider two two-dimensional zero-mean random vectors \( \tilde{x} \) and \( \tilde{y} \) with individual covariances

\[
C_{xx} = \begin{bmatrix} 3 & -1 \\ -1 & 1 \end{bmatrix}, \quad C_{yy} = \begin{bmatrix} 5 & 4 \\ 4 & 5 \end{bmatrix},
\]

which are correlated with \( |r_{xy}| \leq 0.8 \).

In addition, the two random vectors are related according to (3) with

\[
H_x = \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix}
\]

and

\[
H_y = \begin{bmatrix} 1 & 0 \\ 0 & 3 \end{bmatrix}.
\]

Some members of the family of possible joint covariance matrices for the random vector \( \tilde{z} \) with

\[
\tilde{z} = H_x \tilde{x} - H_y \tilde{y}
\]

are visualized in Figure 5 a) by plotting the respective 1-sigma-bounds. Some members of the family of outer covariance bounds derived in this paper are shown in Figure 5 b).
Individual covariance matrices $C_{xx}$ and $C_{yy}$ are given

While Num less than desired number of samples

Draw random numbers $r_{11}, r_{12}, r_{21}, r_{22} \in [-r_{\max}, r_{\max}]$

Calculate the cross covariance matrices

$$
C_{xy} = \begin{bmatrix}
    r_{11} \sqrt{C_{xx,11} C_{yy,11}} & r_{12} \sqrt{C_{xx,11} C_{yy,22}} \\
    r_{21} \sqrt{C_{xx,22} C_{yy,11}} & r_{22} \sqrt{C_{xx,22} C_{yy,22}}
\end{bmatrix}
$$

$$
C_{yx} = C_{xy}
$$

\[ Y \] $C_{yy} C_{xx}^{-1} C_{xy} \leq r_{\max}^2 C_{yy} \quad ?$

\[ N \] Num++

Calculate complete joint covariance matrix

$$
C = \begin{bmatrix}
    C_{xy} & C_{zz} \\
    C_{zy} & C_{yy}
\end{bmatrix}
$$

Figure 4: Structure chart of the naive generation of valid joint covariance matrices for two two–dimensional random vectors with symmetrically constrained correlation.

5 Conclusions

A new method for data validation in the presence of imprecisely known correlations has been proposed, which contains the case of completely unknown correlations [4] as a special case. It is exact, simple to implement, and computationally efficient. The main computational effort is spent by calculating the maximum of a scalar concave function.
